MEMORANDUM

DATE: March 30, 2021
TO: David Leard, ACIP (HNTB)
CC: Steven Granson (HNTB)
FROM: Mark Ingram, PE, PTOE (ATG)
RE: TransModeler Whitepaper

The purpose of this document is to compare Synchro and TransModeler's traffic analysis capabilities to evaluate Bus Rapid Transit (BRT) Operations for the Houston METRO University Line project.

Currently, ATG is scoped to use Synchro to evaluate existing, no-build, and 3 build alternatives. Synchro, while an effective analysis tool, does not have robust, transit features such as semi-exclusive lanes and transit signal priority. As a result, we are proposing a new analysis software approach which consists of utilizing TransModeler in lieu of Synchro.

TransModeler has the capability to evaluate the corridor at an intersection level, like Synchro, while also provides us a more comprehensive tool for operational analysis of corridor segments which comprise of multiple modes of transportation (including transit). All measures of effectiveness (MOE) that could be obtained from Synchro would also be available for TransModeler, and most importantly, there will be no additional level of effort required to complete the analysis using TransModeler over Synchro.

Project Description

The University Corridor is defined as a METRORapid Bus Rapid Transit (BRT) line in the Westpark, Richmond, and Lockwood corridors from the Westchase Park & Ride to the Tidwell Transit Center. It connects to the Wheeler Transit Center, operating east to the University of Houston/Texas Southern University (UH/TSU) campuses. East of UH/TSU, the line operates in the north-south Lockwood corridor, terminating at the Tidwell Transit Center. The alignment is currently proposed to be center-running in semi-exclusive lanes, along with nearly four miles of elevated structure over Buffalo and Hunting bayous, Beltway 8, and several major streets. The line is currently proposed to feature 41 stations.

Alternative Analysis

The alternatives for this project will be developed with the goal of decreasing travel time and increasing the reliability of the University BRT line throughout the corridor. The project team will evaluate vehicular traffic operations and bus operations for a semi-exclusive bus lane for a majority of the corridor, in addition to different operational treatments at signalized intersections. This could include, but is not limited to, transit signal priority (TSP) and queue jumping. Other alternatives may include mixed operations or exclusive transit lanes at some locations.

Measure of Effectiveness

During this planning level phase, three alternatives will be developed, and their performance will be compared using different measures of effectiveness (MOE) to assess transportation impacts for the environmental assessment study. The MOEs will be selected during the development of the Methodology and Assumptions report. Before the MOEs can be selected, the analysis software must be determined. It is important to consider the long-term needs of the project when selecting the appropriate software as some MOEs may not be available once software is selected.

The measure of effectiveness available for each software are comparable, as shown in **Table 1**.

Table 1. Measure of Effectiveness comparison

Measure of Effectiveness	Synchro	TransModeler
Intersection – Volume to Capacity (V/C) Ratio	X	X
Intersection – Approach Delay/LOS	X	X
Intersection – Overall Delay/LOS	X	X
Intersection – Queue Lengths	X	X
Arterial – Segment Volume to Capacity (V/C) Ratio	X	X
Arterial – Segment Speed/LOS	X	X
Arterial – Segment Travel Time	X	X
Arterial – Transit Travel Time		X
Arterial – Transit Average Speed		X

** The table above does not show all of the MOEs Included for each software*

Synchro vs. TransModeler

Though the MOEs available for each software are comparable, the ability to model different transportation facilities and operational features such as exclusive busways, semi-exclusive bus lanes, transit signal priority, and queue jumping is where TransModeler will provide the most benefit. TransModeler has Public Transit features built into the program allowing for a more detailed evaluation of the proposed alternatives.

Synchro does not have the direct ability to evaluate different transit operational strategies; therefore, engineering judgment for model assumptions and adjustment will be required due to the lack of built-in features within Synchro as compared to TransModeler. We have experience in applying engineering judgment in this capacity but feel applying TransModeler would be more transparent in the overall analysis process.

TransModeler

TransModeler Public Transit Features

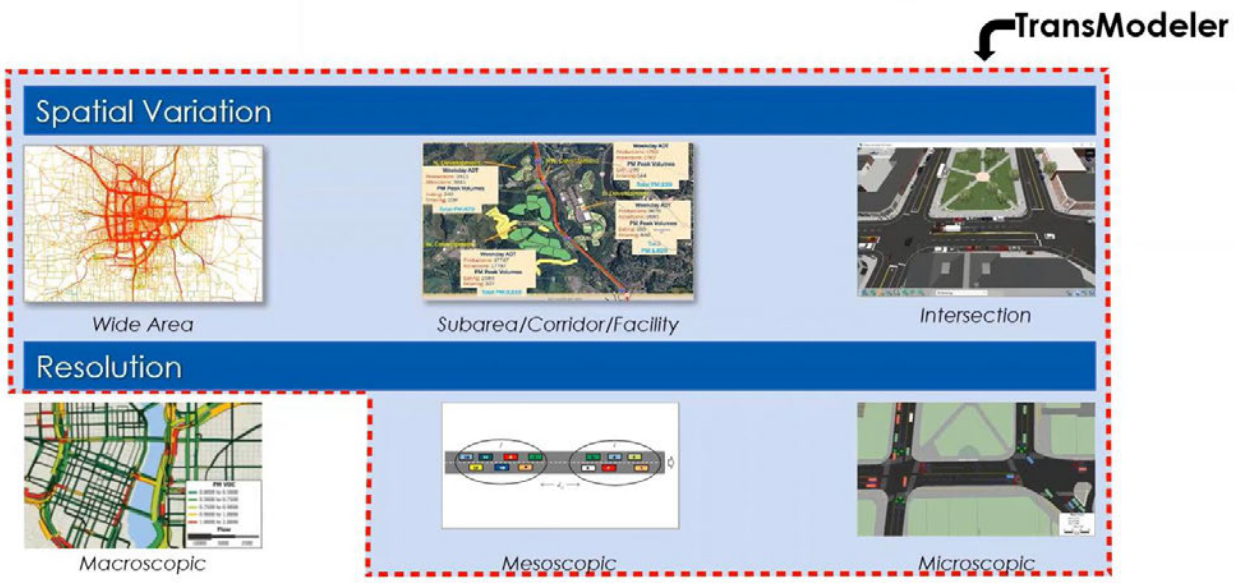
"TransModeler is a multimodal simulator. With TransModeler, you can simulate bus and rail transit systems with frequency or schedule-based service." – TransModeler

- Simulate BRT, exclusive bus lanes, signal priority, and queue jumping
- Report schedule adherence and reliability measures

Figure 1. Screen capture of TransModeler public transit stop

Additional TransModeler Benefits for University Line BRT

- TransModeler automatically creates many elements of the road network; therefore will not require an additional level of effort when comparing directly with Synchro for the same corridor analysis.
- Managing 100 + potential study intersections is easier with GIS architecture that integrates traffic simulation models with a geographic information system (GIS) that has been extended to store, maintain, and analyze transportation and traffic data.
- TransModeler's multi-resolution traffic model can be used to evaluate alternatives at a system level (corridor) but will allow the flexibility to drill down to the segment and intersection level to evaluate different strategies at critical locations
- TransModeler multi-resolution MOE hierarchy: System (Corridor) → Segment → Intersection
- Ability to test different operational strategies: TSP, queue-jumping strategies, BRT vs. mixed operations, signal coordination
- Intersection level-of-service reports consistent with Highway Capacity Manual definitions.
- Define arterial and corridor segments with interactive graphical editing tools to customize segment and corridor level-of-service reports consistent with Highway Capacity Manual definitions.
- Generate clean and easy to read reports, maps, and charts for inclusion in reports and presentation slides
- HD Backgrounds, which will prove to be extremely helpful with both client and public interactions (Highly anticipated for this project)

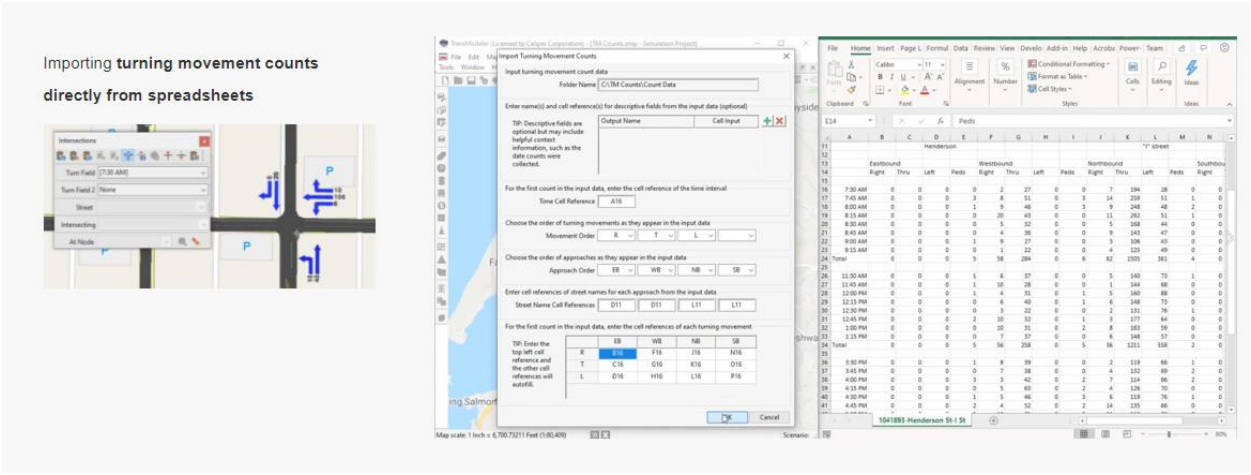


TransModeler network could be progressed to the next stage of this project to minimize the need to re-create the traffic models from scratch when we move into the detailed analysis of the Locally Preferred Alternative.

ATG Experience with TransModeler and the Federal Transit Administration (FTA)

ATG has years of experience with TransModeler for traffic operational analysis. ATG also has experience using TransModeler to evaluate traffic impacts in FTA projects. For example, ATG is currently evaluating the operational impacts of Cap METRO's light rail Orange Line project that runs from north Austin to South Austin.

TransModeler Overview



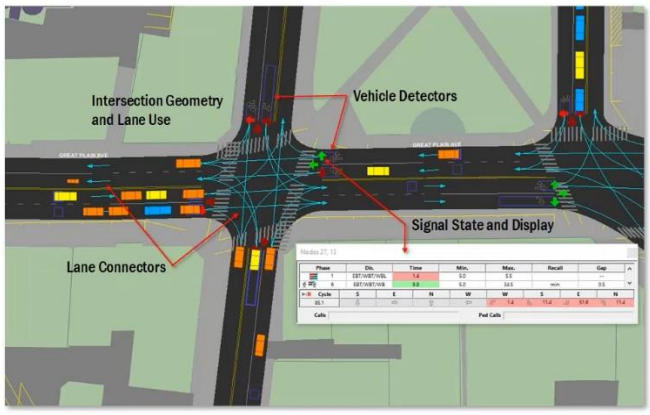
1. Multi-resolution MOE's: Corridor → Segment → Intersection

2. HD Backgrounds, great for client and public use (Highly anticipated for this project)

3. GIS Based and can easily import intersection data from a database. 100+ potential study intersections

4. Calibrated Driving behaviors

Driving Behaviors



- Calibrated for US driving conditions
- Defaults backed by US research
- Corroborated with empirical analysis methods (e.g. HCM)
- Operating capacities and other performance characteristics routinely validated in practice

Vehicle Performance

- Detailed models of US vehicle fleet including auto and heavy vehicles
- Accurate treatments of the effect of grade, horizontal curvature on acceleration, limiting speeds
- Customizable to reflect route restrictions, lane use privileges

5. Detailed Traffic Model for next phase of design

- Ground-truth intersection and lane geometry enables faithful model of operating capacity queue storage, spillback
- Lane connectors represent vehicle paths through intersection, point of conflicts, gap-checking
- Signals and sensors emulate traffic control and vehicle detection in the field

APPENDIX I – TRAFFIC MITIGATION SCENARIO EXHIBITS

APPENDIX I – TRAFFIC MITIGATION SCENARIOS

LANE CONFIGURATION METHODOLOGY

Determining lane configurations at signalized intersections was an iterative process. With anticipated impacts to traffic capacity and intersection LOS, METRO and COH agreed that multiple configuration scenarios should be explored to understand the LOS and resulting impacts from those scenarios before moving forward with a recommended configuration. With some guidance from COH, the general approach to the lane configuration methodology included:

1. Determine lane configuration that would fully mitigate intersection to either a LOS D or baseline LOS condition (2030 No-Build), whichever is less restrictive.
2. Consider multiple lane configurations and their resulting LOS until LOS becomes significant.
3. Compare LOS, V/C ratio, ROW requirements, tree and drainage impacts for each mitigation scenario.
4. No mitigation should come at the expense of requirements and plan for transit, pedestrian or bicycle facilities.

This lane configuration methodology focused only on intersections with projected LOS E or F as modeled by TransModeler in October 2022. Once the intersections were identified, Synchro would be used to model the mitigation scenarios as the results would provide a reasonable idea as to how each mitigation scenario would operate and can be done much quicker. Running a large number of scenarios on an intersection by intersection basis in a traffic microsimulation software would have been overly time consuming and unproductive.

LANE CONFIGURATION ANALYSIS

While the traffic modeling focused on the projected traffic conditions by measuring the LOS at each intersection, the design efforts focused on the impacts to ROW. The impacts to existing trees and drainage were considered at a high level as a detailed analysis with specialists would be needed to determine the actual impacts. In general, the more pavement that a scenario required would result in more impacts to trees and drainage. The tables in this Appendix summarize the mitigation analysis performed.

From the analysis, intersection exhibits for each mitigation scenario were prepared to demonstrate what the lane configurations look like from an aerial view and graphically identify potential ROW impacts. These exhibits are also included in this Appendix. It is noted that exhibits prepared and discussed with COH for those intersections in the 2030 Building conditions that were shown in Synchro to have a LOS E or F and were performing at a poorer LOS than the 2030 No-Build conditions. Additionally, Segment 2 mitigation analysis received a more detailed ROW review as additional roadway design was needed between intersections to properly measure and compare the scenarios.

Drainage Impact Rating

	Build Baseline 2030	Full Mitigation 2030 (same as Baseline)	Partial Mitigation 1: Add one EB left lane	Partial Mitigation 2: Add one EB left lane, one NB left lane, and one WB right lane
Drainage Impact Rating ranks options from 1 to 3 with 1 having least drainage impacts and 3 having most drainage impacts. It is assumed that options with more impervious cover are considered to have more drainage impacts.	**1**	**1**	**2**	**3**

Tree Impact Rating

	Build Baseline 2030	Full Mitigation 2030 (same as Baseline)	Partial Mitigation 1: Add one EB left lane	Partial Mitigation 2: Add one EB left lane, one NB left lane, and one WB right lane
Tree Impact Rating ranks options from 1 to 3 with 1 having least impacts to existing trees and 3 having most tree impacts. Ratings are provided based upon the proximity of the proposed pavement to existing trees; it is assumed that options with pavement closer to existing trees will have more impacts to them.	**1**	**1**	**2**	**2**

University Corridor BRT: MOU

This Memorandum of Understanding (MOU) describes the agreement between METRO and the City of Houston in connection with the METRORapid University Corridor Project (the Project) during the conceptual development and preliminary engineering phase of the project also described as the Federal Transit Administration (FTA) Project Development phase. This MOU also defines the understanding of the shared goals and roles and responsibilities between METRO and the City of Houston. An Interlocal Agreement will be produced at a later date to define the roles and responsibilities of each agency with respect to Project finance, construction, operations, and maintenance.

PROJECT BACKGROUND

The METRORapid University Corridor is a proposed 25-mile METRORapid Bus Rapid Transit (BRT) line from Westchase Park & Ride to Tidwell Transit Center planned by METRO. With dedicated bus lanes and approximately 40 stations, the Project will bring fast, reliable transit to some of Houston's busiest and most densely populated areas utilizing a low or no-emission bus fleet. In addition, the Project will include upgrades to Westchase Park & Ride, Fifth Ward/Denver Harbor Transit Center, and Tidwell Transit Center; and first-and-last mile solutions for access to stations. When complete, the Project will connect to all of METRO's existing light rail transit and BRT lines, thereby supporting the development of a high-frequency, high-capacity transit network across Houston.

CITY OF HOUSTON AND METRO SHARED GOALS AND COMMITMENTS

The City of Houston and METRO are committed to providing equitable regional mobility solutions to residents of the region. The University Corridor provides a generational opportunity to execute on such a commitment.

METRO and the City of Houston share a common goal of providing multi-modal travel options within the City of Houston. To deliver on this goal, the City and METRO have agreed to use the existing right-of-way along the alignment as much as practical to add a high-capacity transit option that prioritizes person throughput. The Project design will align with City's Vision Zero initiative and the City's plan to create walkable places.

The alignment will primarily run on City-owned streets controlled by the City's traffic signal system. Both parties understand that Transit Signal Priority (TSP) will be required to provide fast and reliable service at intersections. METRO and the City therefore commit to providing TSP at intersections where practicable and to the level possible, to improve the speed, reliability, and overall runtime of the proposed BRT Project.

METRO and the City will collaborate on additional project initiatives such as transit oriented development/joint development and stormwater management plans to promote resiliency and equitable development within the corridor. These initiatives will align with the City of Houston's *Resilient Houston Strategy*, *Climate Action Plan*, and *Complete Communities Action Plans* which are solutions-oriented platforms developed by community collaboratives and adopted by City Council on August 29, 2018. These action plans help provide greater access to many community benefits including quality affordable housing and transit options. The City's commitment to Complete Communities provides a basis for a partnership with METRO for the Project as it connects many of those neighborhoods. The Project furthers the goals of this plan and METRO's goal to equitable access to transit services. METRO and the City of Houston will continue to build upon the ongoing coordination and collaboration during the Project Development Phase, through the Final Design, Construction, and Operations and Maintenance phases of the Project.

ROLES AND RESPONSIBILITIES

1. METRO is the Project Sponsor and will be responsible for all project related work during Project Development, Final Design, Construction, Startup, and Operations and Maintenance.

2. METRO and the City of Houston shall meet biweekly, or as otherwise agreed to, to provide a forum to discuss all aspects of the Project during Project Development. Sharing a commitment to expedite the project into the Project Development phase and implement the project sooner, both parties implemented these review meetings at the outset of project coordination; this effort will continue into the subsequent phases of the project.

3. METRO and the City of Houston have established a senior-level committee focused on the successful delivery of the Project. The committee shall address any and all issues that may impact the Project and City-owned right-of-way.

APPENDIX L – THROUGHPUT METHODOLOGY AND FINDINGS

METRONext University Corridor
Throughput Methodology and Findings
March 9, 2022 (updated from February 8, 2022 with information on Segment 5 as requested)

Background

During a METRO/City of Houston (COH) call to initiate discussion on the University Corridor BRT (Bus Rapid Transit) Project held on June 11, 2021, METRO explained the need for the BRT to have a dedicated guideway. METRO explained the most cost-effective approach to develop the dedicated lanes would be to dedicate two general purpose lanes to BRT, especially in areas where right-of-way is limited. This approach would minimize right-of-way acquisitions and may help enhance roadway safety as well as other COH goals. The COH participants expressed their support for the project and for converting a traffic lane to a dedicated BRT lane. COH staff stated COH leadership would need some documentation to help it make an argument to dedicate the travel lanes to BRT. The COH suggested METRO compare the person throughput of a single lane of general-purpose traffic against the person throughput of the BRT as one way to justify the COH's support.

Methodology

There are two general ways to compare the throughput of a general-purpose travel lane to the throughput of a BRT guideway lane.

1. Calculate the Theoretical Maximum of each mode
2. Estimate the future BRT ridership and compare it to the existing vehicle throughput

<u>Method 1</u>
The first method of comparison is to calculate the maximum throughput of each mode. This calculation is straightforward as METRO would compare the throughput of the travel lane to the throughput of the BRT lane.

The throughput of a general-purpose travel lane on a signalized arterial is impacted primarily by the lane width and green time of the signal. For purposes of this comparison the calculation would use the COH's preferred lane width inside I-610 of 10 feet and assume a standard distribution of green time to traffic in both directions. Using these factors, the typical maximum throughput would be approximately 850 vehicles per hour. As suggested by COH, METRO should assume 1 person per vehicle for a maximum person throughput of 850 vehicles, one person per vehicle for a total throughput capacity of 850 people per hour.

The throughput of a BRT lane is calculated by multiplying the number of BRT vehicles per hour by METRO's maximum load per vehicle. Using a BRT headway of 6 minutes translates to 10 BRT vehicles per hour (note, as the system grows, METRO would provide the infrastructure to operate two vehicles consistently, which could increase the BRT capacity to 20 vehicles per hour). With a maximum capacity of 80 people per vehicle, the person throughout would be at 10 times 80 or 800 people per hour up to 20 times 80 or 1,600 people per hour. As the system grows and additional extra buses are added, the throughput would increase.

Implementation of Method 1

The basic calculations are described above. The variance in BRT throughput is large and illustrative of the potential capacity for BRT to dramatically increase person throughput when compared to personal vehicles. This method could be applied equally across the corridor because it is theoretical, and the conditions of the corridor are consistent with respect to travel lanes.

Method 2

The second method of comparison is to calculate projected ridership against existing traffic. This calculation is more complex than Method 1 as it requires several steps to develop the number of passengers on each BRT vehicle.

Developing the existing throughput for the travel lane requires gathering existing traffic data and processing it in Synchro to determine the current number of vehicles traveling through the intersection in the same directions of travel as the BRT and determining the peak direction of travel. This figure would be divided by the number of lanes to estimate the vehicles per lane. As stated above the number of vehicles equals the person throughput.

Developing the estimated throughput for the BRT lane is a three-step process because the FTA (FEDERAL TRANSIT ADMINISTRATION) modeling tool, called Simplified Trips on Project Software, or "STOPS," does not produce peak hour ridership. The steps in the process include:

1. Estimate a peak hour factor and determine the peak direction of travel.
2. Apply the peak hour factor to the station level boarding figures developed in STOPS.
3. Calculate the number of riders traveling through a selected intersection to determine the BRT throughput. This is done by adding boarding passengers and subtracting alighting passengers to determine the peak load. The peak load equals the BRT throughput.

Implementation of Method 2

METRO has completed the acquisition and evaluation of existing traffic counts. METRO will need to determine the number of vehicles per lane. To make this exercise more cost effective, it is recommended the throughput be calculated at the most congested intersection in Segments 2, 3, 4 and 5 as described above. Segment 1 is excluded because the BRT would be operating in METRO owned right-of-way on a new guideway built exclusively for BRT vehicles. Figure 1 shows the project limits and segments.

METRO is currently developing the projected ridership. Once the ridership modeling process is complete METRO should calculate the BRT throughput at the most congested intersections identified above and at the peak load point in each of the four segments. This approach provides a direct comparison to the traffic throughput and provides a comparison of the BRT's peak load point.

Figure 1: University Corridor Project Limits

Selected Approach

After reviewing the proposed methodology, the COH via David Fields selected Method 2, which was to compare actual traffic counts to the projected project ridership.

Analysis Findings

The METRO PMC performed the analysis to support the findings described below. The PMC collected traffic counts during the AM and PM peak periods, 7 AM – 9 AM and 4 PM to 6 PM. The counts were taking over two days, September 1st, 2021, and September 9th, 2021, due to the size of the corridor. The data was further analyzed to identify the peak hour for each intersection (see Appendix A). Based on the peak hour counts, the PMC selected the highest volume for Segment 2, Segment 3, Segment 4, and Segment 5 as follows:

- Segment 2 - Richmond Avenue at Kirby Drive
- Segment 3 - Wheeler Avenue at San Jacinto Street
- Segment 4 - Lockwood Drive at Navigation Boulevard
- Segment 5 – Lockwood Drive at Nichols Street

The equation to calculate the peak hour volume per lane on the legs of each intersection that would also be used by the BRT is the total volume of lanes traveling through the intersection divided by number of lanes, which equals volume per lane. Volumes on dedicated left turn lanes were removed from the total volumes because left turns would remain at each of the four intersections.

The PMC used the FTA's STOPS to produce the ridership forecast for the project. The PMC then calculated the peak period ridership at the proposed BRT station nearest to each of the above intersections.

Table 1 shows the peak volume per lane for the AM and PM peak periods and the comparable peak BRT ridership. The results show the BRT ridership to be higher than the peak lane volumes in Segments 2, 3 and 4. In Segment 5, the calculated peak traffic volume exceeds the forecasted BRT peak period ridership.

Table 1: Comparison of Peak Period Vehicles Per Lane to Forecasted BRT Ridership

Segments	Direction of Travel	Number of Through lanes[1]	Total Vehicles by Direction during Peak Hour [2]		Existing Vehicles Per Lane during Peak Hour		Total Passengers on BRT during Peak Hour from 2019 STOPS Model Results
			AM	PM	AM	PM	
Segment 2 - Richmond Avenue at Kirby Drive	Richmond Ave EB	3	495	659	165	**220**	**272**
	Richmond Ave WB	3	282	451	94	150	
Segment 3 - Wheeler Avenue at San Jacinto Street	Wheeler Ave EB	2	466	623	233	**312**	**423**
	Wheeler Ave WB	2	384	432	192	216	
Segment 4 - Lockwood Drive at Navigation Boulevard	Lockwood Dr NB	2	332	403	166	**202**	**260**
	Lockwood Dr SB	2	431	282	216	141	
Segment 5 - - Lockwood Dr at Nichols St	Lockwood Dr NB	3	288	733	96	244	**230**
	Lockwood Dr SB	3	458	480	153	160	

Notes:

1 – Existing number of lanes including through lanes and shared through/right lanes only as one of these lanes would be replaced by a dedicated BRT lane. Exclusive right and left turn lanes have NOT been included.

2 – Existing volumes are the total vehicles traveling in the through lanes identified in the previous column. Vehicles turning in dedicated left or right turn lanes are NOT included in the totals.

- Intersections with the highest congestion (largest total intersection volume) for each segment were collected for the throughput analysis

- Throughput calculations are based on approach volumes and do not take effects of green time reallocation into consideration
